The present invention relates to a novel pyrimidine derivative, a method for producing the same, its use as a herbicide and an intermediate of the same.

European Patent Application No. 0223 406A1, 0249 708A1, 0249 707A1, etc. disclose that pyrimidine derivatives can be used as an active ingredient for herbicides.

However, these compounds are not always said to be satisfactory because they are insufficient in herbicidal activity.

On the other hand, a large number of herbicides for crop lands or non-crop lands are now in use. However, there are many kinds of weeds to be controlled and generation of the weeds extends over a long period of time, so that development of herbicides having a higher herbicidal activity and a broader herbicidal spectrum than before is being desired. Further, in recent years, no-till cultivation has been carried out for the purposes of saving labor, extending cultivation period, preventing soil erosion, etc. Therefore, it is being much desired to develop herbicides having both a high post-emergence herbicidal activity against weeds and pre-emergence herbicidal activity, their excellent residual activity at high level, and a high selectivity to the undesired weeds as compared with the desired crops.

In view of the situation like this, the present inventors have extensively studied, and as a result, have found that pyrimidine derivatives represented by the following formula (I) are compounds having an excellent herbicidal activity and having few foregoing defects, and that some of the derivatives have a high selectivity to the undesired weeds as compared with the desired crops. That is, the pyrimidine derivative can control the undesired weeds widely generated in crop lands or non-crop lands at low dosage rates, has a broad herbicidal spectrum and also can safely be used for no-till cultivation. The present invention is based on this finding.

The determination of the herbicidal activity and phytotoxicity was carried out as follows: When the states of emergence and growth of treated test plants (weeds and crops) at the time of determination were completely the same as or hardly different from those of untreated test plants, the value of determination was taken as "0". When the treated test plants were completely killed, or their emergence and growth were completely inhibited, the value of determination was taken as "5", and an interval between "0" and "5" was divided into four stages, i.e. "1", "2", "3" and "4". The evaluation was thus made in six stages.
